Investigating the propagation of pre-steepened waveforms in the vicinity of a supersonic jet

ROMAIN FIVET\textsuperscript{1}, The University of Texas at Austin, WOUTIjn J. BAARS\textsuperscript{2}, The University of Melbourne, DAVID SILVA\textsuperscript{3}, CHARLES E. TINNEY\textsuperscript{4}, The University of Texas at Austin — Recent studies [Baars et al. 2013] on jet noise have shown that despite the presence of crackle, cumulative nonlinear effects are absent along the peak noise path of laboratory-scale jets. This study quantifies the influence pre-steepened waveforms have on the shock formation distance $\tau$, an effective Goldberg number $\Lambda$, and the intensity of crackle. The pressure decay along the peak noise path (cylindrical/spherical) is a pre-requisite to this study since it greatly influences $\tau$ and $\Lambda$. The outward propagation of broadband, pre-steepened waveforms, are obtained by numerically applying the generalized Burgers equation. Meanwhile, a large-eddy-simulation of a Mach 1.74 heated supersonic jet is interrogated by way of an innovative wavelet filter [Grizzi & Camussi, JFM 2012] in order to isolate the acoustically relevant components of the flow and observe the decay of the OASPL along the peak noise path.
